```

import UIKit

internal class ViewController : UIViewController {
    // MARK: - Properties
    internal let cars: <error type>

    @IBOutlet internal var stackView: UIStackView!
    @IBOutlet internal var model: UISegmentedControl!
    @IBOutlet @objc(getter, setter, or notifier) internal var modelClass: UISegmentedControl!
    @IBOutlet internal var mileageLabel: UILabel!
    @IBOutlet internal var mileage: UISlider!
    @IBOutlet internal var condition: UISegmentedControl!
    @IBOutlet internal var valuation: UILabel!

    override internal func viewDidLoad() {
        super.viewDidLoad()
    }
}

```

Read more on Apple's Official Guide: [How to use those classes to print currency symbol? "nil" CurrencyFormatter.outputFormatter = CurrencyFormatter.create\(locale: Locale\(identifier: "es\\_ES"\)\) print\(price.toCurrency\(\) ?? "nil"\) \\$12,423.42 USD12,423.42 12.423,42 € 12 423,42 EUR 12\\_423.42 US dollars 12 423.42 Euro "nil"\) let formatter = CurrencyFormatter.create\(locale: Locale\(identifier: "de\\_DE"\), groupingSeparator: ".", decimalSeparator: ",", style: .currencyPlural\) print\(price.toCurrency\(formatter: formatter\)\)](#) The NSNumber class is able to store signed and unsigned char, short, integer, int, long and long long data types and also float, double and Bool values. "nil") CurrencyFormatter.outputFormatter = CurrencyFormatter.create(locale: Locale(identifier: "de\_DE"), groupingSeparator: ".", style: .currencyISOCode) print(price.toCurrency())

Now, the example above is going to display the default currency format (USD). NumberFormatter objects can also impose ranges on the numeric values cells can accept. To show a number in proper currency format, we are going to use following classes. Let's look at this example: let price = 12.34 as NSNumber let formatter = NumberFormatter() formatter.numberStyle = .currency print(formatter.string(from: price!))

The primary purpose of the NSNumber class is to allow the storage of primitive numerical data in the form of an object. = nil, style: NumberFormatter.Style.currency -> NumberFormatter { let outputFormatter = NumberFormatter(locale: locale outputFormatter.decimalSeparator = decimalSeparator ?? formatter.locale = Locale(identifier: "br\_IN") print(formatter.string(from: price!)) //Output â' 12.34

We can actually display the whole currency in Indian language: formatter.locale = Locale(identifier: "bn\_IN") print(formatter.string(from: price!)) //Output অসহস্রঃ অশোঁশঃ Here is the full list of iOS Locale Identifiers on Github: [currency NSNumber NSNumberFormatter « Previous Next » Xcode 10.2.1 \(10E1001\), Swift 5 import Foundation class CurrencyFormatter { static var outputFormatter = CurrencyFormatter.create\(\) class func create\(locale: Locale = Locale.current, groupingSeparator: String? = nil, decimalSeparator: String? = nil, style: .currencyISOCode\) class func create\(locale: Locale = Locale.current, groupingSeparator: String? = nil, decimalSeparator: String? = nil, style: .currencyPlural\) print\(price.toCurrency\(\)\)](#)

The representation encompasses integers, floats, and doubles; floats and doubles can be formatted to a specified decimal position. CurrencyFormatter.outputFormatter = CurrencyFormatter.create(style: .currencyISOCode) print(price.toCurrency())

NSNumber is a subclass of NSNumber that offers a value as any C scalar (numeric) type, = nil, decimalSeparator: String? To display currency, we will need to show the currency symbol (\$, €, ¥, £) for the current locale and for that we use NSNumberFormatter, which is now NumberFormatter class. So, by default 9,992,098.0 will be displayed as 9992098.0. \$, we need to use the NumberFormatter (NSNumberFormatter in older Swift) class to convert your number into a formatted String for a text field. locale.decimalSeparator outputFormatter.groupingSeparator = groupingSeparator ?? Declaration class NSNumber : NSNumber Read more on Apple's Official Guide: [NumberFormatter](#) A formatter that converts between numeric values and their textual representations. Also, When we display a number in Swift in Float, Double, or Int, it will display the numbers without grouping separators. For example, let's display Indian Rupee symbol. locale.groupingSeparator outputFormatter.numberStyle = style return outputFormatter } extension Numeric { func toCurrency(formatter: NumberFormatter = CurrencyFormatter.outputFormatter) -> String //Output \$12.34 If we want to display currency in whole number, we can use this: formatter.locale = Locale(identifier: "es\_CL") print(formatter.string(from: price!)) //Output \$12 We can also define other currency symbol. It defines a set of methods specifically for setting and accessing the value as a signed or unsigned char, short int, long int, long long int, float, or double or as a BOOL. It also defines a compare(·) method to determine the ordering of two NSNumber objects.
